Reducing visual complexity for improved search efficiency.

Designers should strive to reduce the visual complexity of their websites to a minimum, while taking into account user preferences, in order to improve search efficiency and information recall for the users.

About this paper

The authors conducted an online study to investigate the impact of visual complexity on search efficiency and information recall.

The results showed that the search efficiency of those who preferred simple websites was more negatively affected by highly complex websites than those who preferred high visual complexity.

Which part of the paper did the design guideline come from?

"Our analysis revealed that website complexity has a significant negative effect on search efficiency, controlling for our first hypothesis (see Table 2). A linear mixed-model ANOVA revealed the significant effect of complexity on search responses, $F(1, 89) = 4.44, p < .05$. Participants were fastest on simple websites ($M = 4.26, SD = 4.24$) and slowest on highly complex websites ($M = 7.38, SD = 7.04$), regardless of their preferred complexity level (...) (Section 4)
